

Data Science I: Homework 2

Neal Kuperman

February 4, 2026

Problem 1: College Data Analysis

Consider the `College` data from the ISLP package. Details about the data is described on page 65 of the ISLP textbook for this class (<https://islp.readthedocs.io/en/latest/datasets/College.html>). We would like to *predict* the number of applications received using the other variables. 80% of the data (randomly generated) will be treated as training data. The rest will be the test data.

- (a) Fit a linear model using least squares and report the estimate of the test error.
- (b) Fit a tree to the data. Summarize the results. Unless the number of terminal nodes is large, display the tree graphically. Report its MSE.
- (c) Use Cross validation to determine whether pruning is helpful and determine the optimal size for the pruned tree. Compare the pruned and un-pruned trees. Report MSE for the pruned tree. Which predictors seem to be the most important?
- (d) Use a bagging approach to analyze the data with $B = 500$ and $B = 1000$. Compute the MSE. Which predictors seem to be the most important?
- (e) Repeat (d) with a random forest approach with $B = 500$ and $B = 1000$, and $m \approx p = 3$.
- (f) Compare the results from the various methods. Which method would you recommend?

Note(s)

The data is statistics for a large number of US Colleges from the 1995 issue of US News and World Report. Table 1 contains the variable descriptions, which can also be found on the [ISLP documentation](#). Tables 2 - 4 contain the descriptive statistics for the data.

Variable	Description
Private	A factor with levels No and Yes indicating private or public university
Apps	Number of applications received
Accept	Number of applications accepted
Enroll	Number of new students enrolled
Top10perc	Pct. new students from top 10% of H.S. class
Top25perc	Pct. new students from top 25% of H.S. class
F.Undergrad	Number of full time undergraduates
P.Undergrad	Number of part time undergraduates
Outstate	Out-of-state tuition
Room.Board	Room and board costs
Books	Estimated book costs
Personal	Estimated personal spending
PhD	Pct. of faculty with Ph.D.s
Terminal	Pct. of faculty with terminal degree
S.F.Ratio	Student/faculty ratio
perc.alumni	Pct. alumni who donate
Expend	Instructional expenditure per student
Grad.Rate	Graduation rate

Table 4: College Dataset Descriptive Statistics (Part 3)

Solution

Due to the wide range of values in the college data, the college data was scaled using the standard scalar transform from scikit-learn.

Table 5: OLS Regression Results

The test MSE for the linear regression model is 642,753.9 and the test R^2 is 0.946.

1 b)

Three initial regression trees were created with maximum depths of 3, 10, and unrestricted. Setting `max_depth=None` allows the algorithm to expand nodes until all leaves are pure or contain fewer than `min_samples_split` samples. The unrestricted tree reached a depth of 20 with 537 leaves. Training and test MSE and R^2 for the three trees are given in table 6. Figure 1 shows the tree with max depth of 3. The tree with an unrestricted max depth and max depth of 10, not displayed due to their complexity, have similar performance on the training data and outperform the smaller tree in both test MSE and test R^2 . The low training MSE and high training R^2 suggest that the larger trees are overfitting to the training data, however, they are still able to generalize well to the test data. The most important feature for all trees is the numbers of applications accepted and the percentage of new students from the top 10% of the high school class (Table 7).

Max Depth	Training MSE	Test MSE	Training R ²	Test R ²
3	1.579×10^6	1.952×10^6	0.90	0.84
10	9,582	1.0699×10^6	0.999	0.91
unrestricted (20 leaves)	0.0	1.083×10^6	1.0	0.91

Table 7: Feature Importance for Regression Trees

1 c)

To evaluate the effect of pruning, we applied cost-complexity pruning to the tree with unrestricted max depth. Figure 2 shows the pruned best tree, which has an alpha value of 17,157.520. Table 8 shows the training and test MSE and R^2 for both the unpruned and pruned trees. Pruning improved test MSE and test R^2 , indicating a reduction in overfitting. Table 9 shows the feature importance for the pruned tree. The top six features (Accept, Top10perc, Top25perc, F.Undergrad, Outstate, and Expend) are identical to those in the unpruned tree. Personal is the only additional feature with non-zero importance in the pruned tree that was not among the top features in the unpruned model.

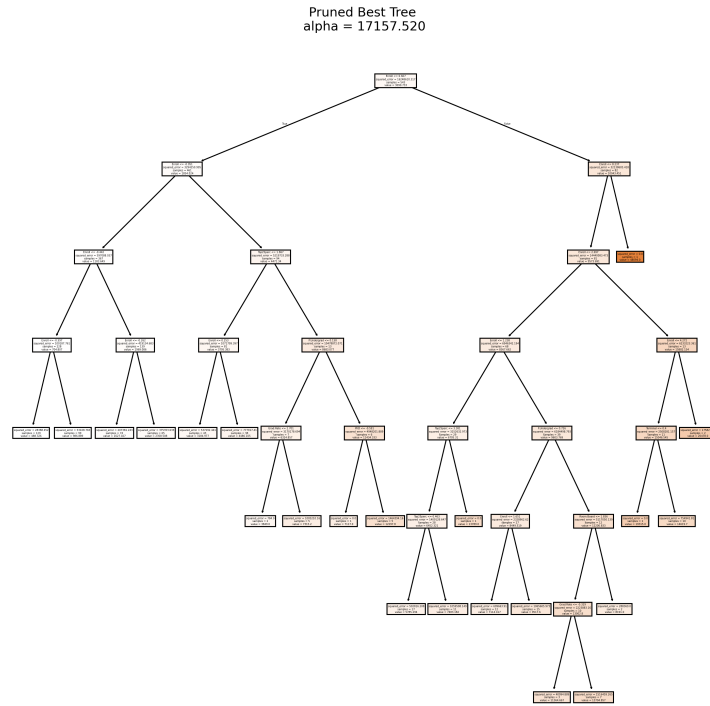

Figure 2: Pruned Best Tree

Tree Type	Training MSE	Test MSE	Training R^2	Test R^2

Table 9: Feature Importance for Pruned Regression Tree

1 d)

Table 10 shows the training and test MSE and R^2 for the regression trees with bagging for B values of 500 and 1000. Both trees have similar training and test MSE and R^2 , indicating that a value of $b=500$ is sufficient for this data. Table 11 shows the feature importance for the regression trees with bagging for B values of 500 and 1000. The top six features (Accept, Enroll, Top10perc, Top25perc, Expend, and Grad.Rate) are the same for both trees.

B value	Training MSE	Test MSE	Training R^2	Test R^2
500	351,729.95	655,166.13	0.978	0.945
1000	325,604.62	652,137.78	0.980	0.945

Table 13: Feature Importance for Regression Trees with Random Forest (n estimators=500 and n estimators=1000)

1 f)

I would recommend the random forest with bagging classifier. Although the linear regression model has a similar MSE for the test data, the random forest will work with non-linear relationships making it a more robust classifier. The major benefit to the linear regression model is the interpretability of the coefficients.

Method	Training MSE	Test MSE	Training R^2	Test R^2
Linear Regression	1,251,247	642,754	0.923	0.946
Unpruned Best Regression Tree ($\alpha = 17,157.520$)	0.0	1,082,900	1.0	0.909

Random Forest n_estimators=1000	386,329	1,086,991	0.976	0.909

Table 14: MSE and R^2 for Different Regression Methods

Problem 2: Admission Data Analysis

Consider the business school admission data available in the admission.csv. The admission officer of a business school has used an “*index*” of undergraduate grade point average (GPA,X1) and graduate management aptitude test (GMAT,X2) scores to help decide which applicants should be admitted to the school’s graduate programs. This index is used to categorize each applicant into one of three groups - admit (group 1), do not admit (group 2), and borderline (group 3). We will take the last ***four*** observations in ***each category*** as test data and the remaining observations as training data.

- (a) Perform an exploratory analysis of the training data by examining appropriate plots and comment on how helpful these predictors may be in predicting response.
- (b) Perform an LDA using the training data. Superimpose the decision boundary on an appropriate display of the data. Does the decision boundary seem sensible? In addition, compute the confusion matrix and overall misclassification rate based on both training and test data. What do you observe?
- (c) Repeat (b) using QDA.
- (d) Fit a KNN with K chosen optimally using test error rate. Report error rate, sensitivity, specificity, and AUC for the optimal KNN based on the training data. Also, report its estimated test error rate.
- (e) Compare the results in (b), (c) and (d). Which classifier would you recommend? Justify your conclusions.

Note(s)

The following metrics are useful for evaluating the performance of classifiers. We will use some of them when evaluating the performance of the KNN classifier.

Error rate: percentage misclassification

$$\frac{\text{Misclassified}}{\text{Total}} = 1 - \text{Accuracy}$$

Sensitivity (*true positive rate*): measures the proportion of actual positives correctly identified as positive

$$\frac{\text{Number of true positives}}{\text{Number of true positives} + \text{Number of false negatives}}$$

Specificity (*true negative rate*): measures the proportion of actual negatives correctly identified. Note: Also called recall.

$$\frac{\text{Number of true negatives}}{\text{Number of true negatives} + \text{Number of false positives}}$$

Precision: Ratio of the correctly predicted class to the total predicted class

$$\frac{\text{Number of true positives}}{\text{Number of true positives} + \text{Number of false positives}}$$

F1 Score: A harmonic mean between the Precision and Recall score

$$2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

ROC Curve: A Receiver Operating Characteristic (ROC) curve is a graphical plot that illustrates the diagnostic ability of a binary classifier system by plotting the true-positive rate (sensitivity) against the false-positive rate ($1 - \text{specificity}$) across various decision thresholds¹.

Solution

2 a)

The following table and plots were generated to explore the admission training data

- Table 15: Descriptive statistics for the admission data.
- Figure 3: Distribution plots for the GPA, GMAT, and Group.
- Figure 4: Scatter plot of GPA vs GMAT.
- Figure 5: Box plots for the GPA and GMAT by Group.

We can see that the data is relatively balanced across groups and that there is good separation between the groups (see Figure 4). Additionally, There is not a large variation in the distribution of GPA and GMAT within and across each group. In particular, the scatter plot shows that, given a good classifier, we should be able to separate the groups well.

	GPA	GMAT	Group
count	85	85	85
mean	2.97	488.45	1.94
std	0.42	81.52	0.82
min	2.13	313	1
25%	2.60	425	1
50%	3.01	482	2
75%	3.30	538	3
max	3.80	693	3

Table 15: Admission Data Descriptive Statistics

¹https://en.wikipedia.org/wiki/Receiver_operating_characteristic

Figure 3: Training Admission Data - Distribution Plots

Figure 4: Training Admission Data - Scatter Plot of GPA vs GMAT

Figure 5: Training Admission Data - Box Plots of GPA and GMAT by Group

2 b)

Figure 6 shows the Admission Data with LDA decision boundaries. The boundaries look reasonable, but there is room for improvement as the misclassification rate for the test data was 25% and an AUC of 0.979. From the test data, we can see that the LDA has the most trouble classifying group 2, however three of the four test data points live on or near the decision boundary. It may be worthwhile exploring different train/test splits to study how much role the sampling has on the classifier's performance. Tables 16, 17, and 18 show the confusion matrices for the training and test data respectively and the misclassification rates for the training and test data.

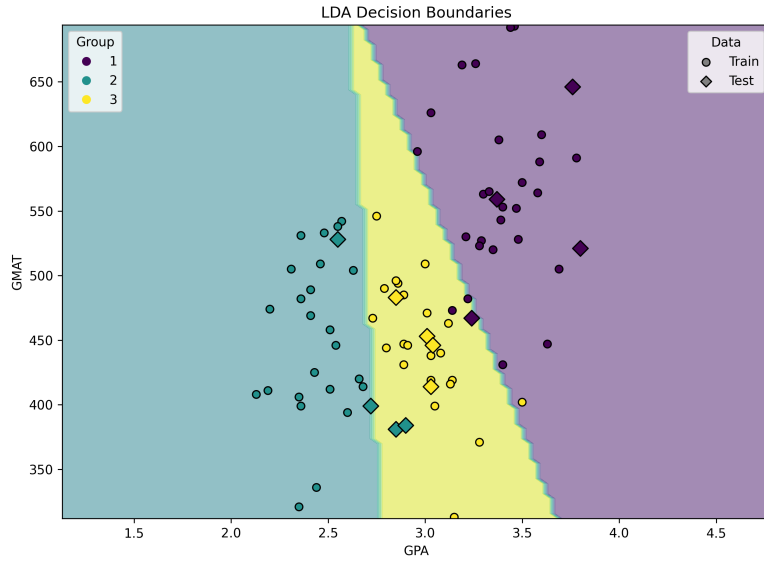

Figure 6: Admission Data with LDA Decision Boundaries

Table 17: LDA Confusion Matrix for Test Data

Data	Misclassification Rate
Test	25.00%
Train	4.11%
Total	7.06%

Table 18: LDA Misclassification Rates

2 c)

Figure 7 shows the Admission Data with QDA decision boundaries. The quadratic boundaries provide better separation between classes compared to the linear boundaries from LDA. This is further reflected in the confusion matrices (tables 19 and 20) and misclassification rates (table 21). Going from LDA to QDA, the misclassification rate for the test data decreased from 25% to 16.67% and the total misclassification rate decreased from 7.06% to 4.71%. The AUC for the QDA model on the test data is 0.958, slightly lower than the LDA model's AUC of 0.979.

Figure 7: Admission Data with LDA Decision Boundaries

Table 20: QDA Confusion Matrix for Test Data

Data	Misclassification Rate
Test	16.67%
Train	2.74%
Total	4.71%

Table 21: QDA Misclassification Rates

2 d)

For a KNN classifier, the predicted probability for a class is the proportion of the K neighbors belonging to that class, i.e.,

$$P(\text{class } k \mid x) = \frac{\text{number of neighbors in class } k}{K}$$

The ROC curve is generated by varying the probability threshold required to classify a point as positive. When building the ROC curve, we vary $t \in [0, 1]$ with the decision rule: predict Class n if $P(\text{Class } n \mid x) \geq t$.

For a multiclass classification problem, we can no longer generate a single ROC curve since it is based on a binary classifier. We can use the one-vs-all scheme, which compares each class against all the others (combined as one)².

NOTE: Since KNN is a distance based method, we want to make sure that GMAT and GPA are on similar scales. We are going to use the standard scaling method from scikit learn on our training and test data. All plots are generated using data transformed back into the original coordinates.

3	0.8636	1.0000	Test Error Rate	0.0833

Table 24: KNN Classification Metrics

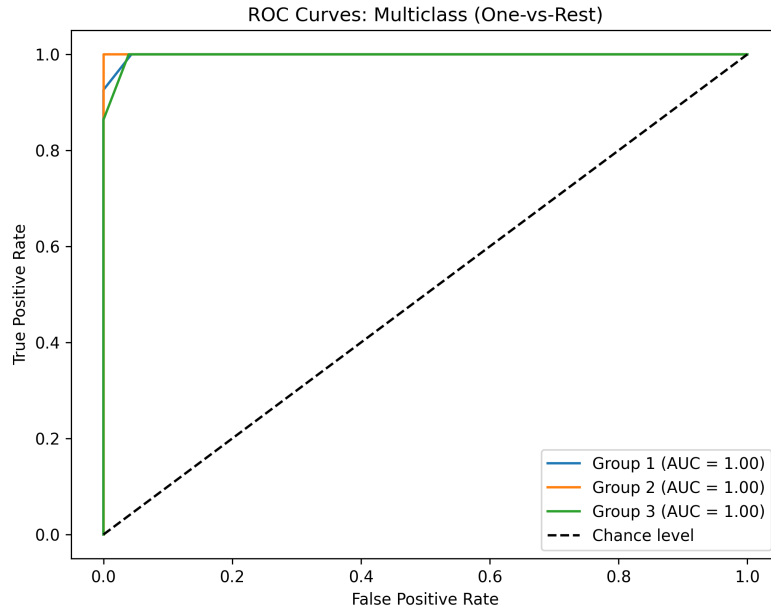

Figure 10: KNN: ROC Curve

2 e)

Fig 11 shows the decision boundaries for LDA, QDA, and KNN and tables 25 and 26 show the performance metrics and confusion matrices for the training and test data respectively. We can see that the KNN classifier outperforms the other two classifiers, with the KNN having a misclassification rate for the test data of 8.3% compared to 16.7% and 25% for QDA and LDA respectively. Given the lower test error rate and overall error rate, I would recommend the KNN classifier.

(a) LDA

(b) QDA

(c) KNN

Figure 11: Decision Boundaries for LDA, QDA, and KNN

Method	Train		Test		Total	
	Error	AUC	Error	AUC	Error	AUC
LDA	4.11%	0.997	25.00%	0.979	7.06%	0.991
QDA	2.74%	0.999	16.67%	0.958	4.71%	0.992
KNN (K=2)	4.11%	0.999	8.33%	0.938	4.71%	0.989

Table 25: Classification Performance by Method

		Training			Test		
		Truth			Truth		
		1	2	3	1	2	3
LDA							
	Predicted						
	1	25	0	1	3	0	0
	2	0	24	0	0	2	0
	3	2	0	21	1	2	4
QDA							
	Predicted						
	1	26	0	1	4	0	0
	2	0	24	0	0	2	0
	3	1	0	21	0	2	4
KNN (K=2)							
	Predicted						
	1	27	0	0	4	0	0
	2	0	24	0	0	3	1
	3	2	1	19	0	0	4

Table 26: Confusion Matrices by Classification Method

My code can be found in the jupyter notebook HW_2.ipynb hosted at https://github.com/nealkuperman/Data_Science_I/tree/main/HW/HW_2. The python script has the same code as the jupyter notebook without the markdown cells and in-line figures and tables.
